

Make It Do Something

Demo Screenshots

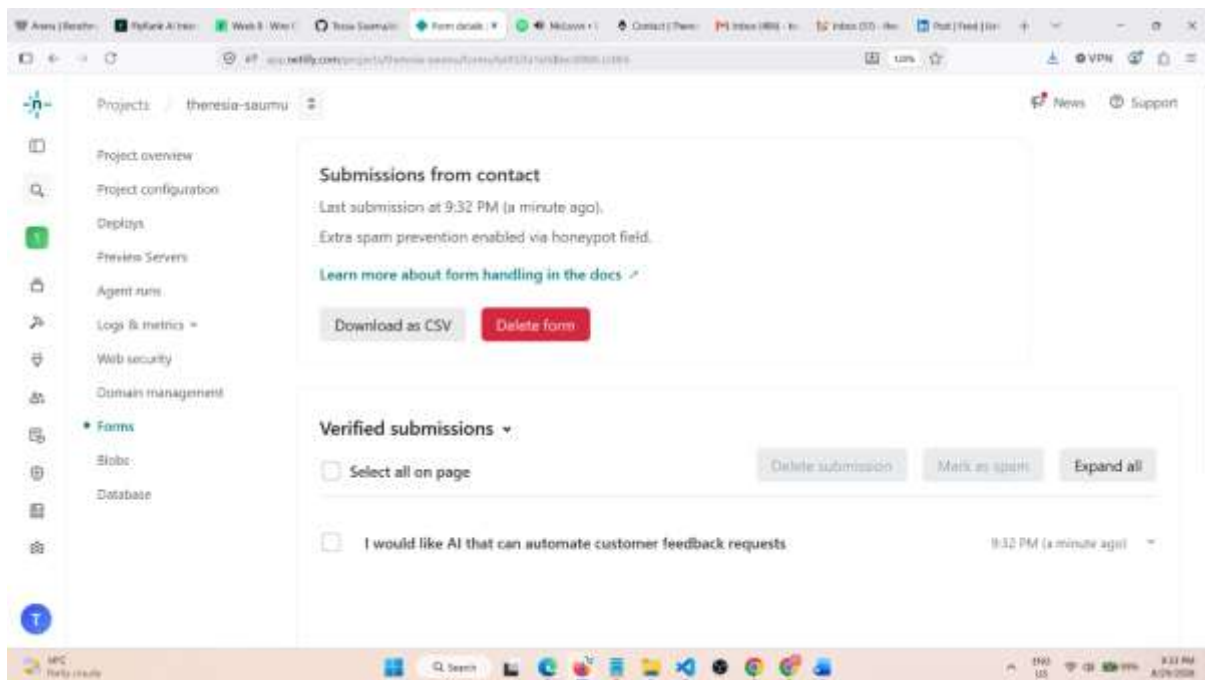

Note: These screenshots are all from the same run, see timestamps for proof (9:32-9:35PM)

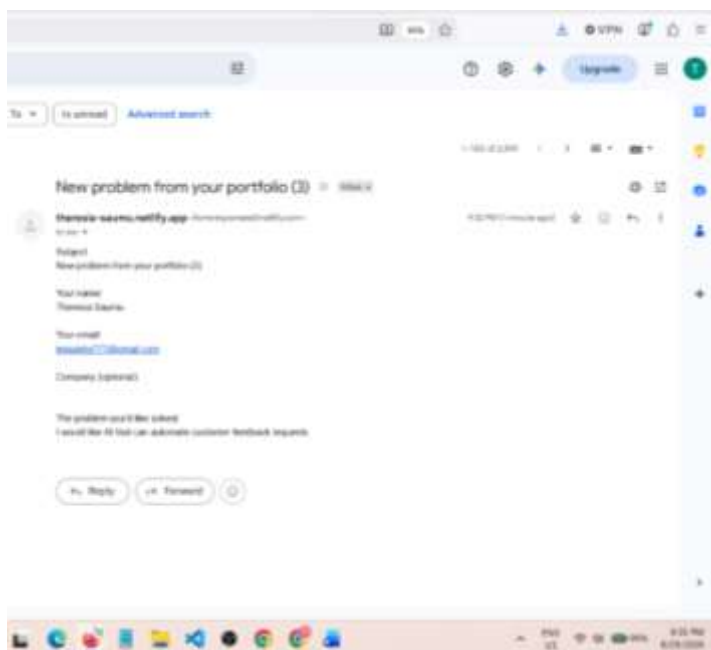

Screenshot 1: Information input

Screenshot 2: Submitting form

Screenshot 3: Netlify forms indicating form successfully submitted

Screenshot 4: Email receiving submitted form's information correctly formatted

Backend Explainer

Backend can be thought of as the backroom or engine of the website. It lives behind what the user sees and handles functionality that wouldn't otherwise be possible. For example having a database which can store data.

In my portfolio site I have used Netlify Forms instead of having to create a backend just for the contact form this is the platform ready solution that is available on the free tier.

Here Netlify Forms is the backend for my site that allows the site to have a custom contact form and saves information to Netlify's storage and sends an alert to my email when a new form is submitted.

The way data will flow is from the end user's screen to the frontend through a connection to the backend. Netlify Forms stores it and sends an alert to my email and a response back to the frontend saying that the form was submitted successfully or if an error occurred for example so that the frontend can display a successfully sent message. Netlify Forms also does spam checking so this is done when processing the request.
